

The influence of low-energy buildings on the future Danish energy system

David Drysdale, PhD fellow

Aalborg University

Sustainable Energy Planning Research Group

Outline of the presentation

- Overview of the study
- The methodology of the study
- Analysis
- Results
- Main points
- Future work
- Questions and comments

AALBORG UNIVERSITY
DENMARK

Overview of the study

- ✓ I assessed the **impacts** of new low-energy buildings (nZEBs) in a **future highly-renewable energy system in 2050**
- I did not investigate the impacts in a **shorter time span**, i.e. in the next 10-15 years

AALBORG UNIVERSITY
DENMARK

Method

Defining the projected changes

1. The Danish **building stock** from today to 2050
2. The potential **future highly-renewable energy system** of Denmark in 2050

Analysis procedure

3. I tested different **heat demand levels** in the new buildings to understand their impact in the highly-renewable energy system in the year 2050

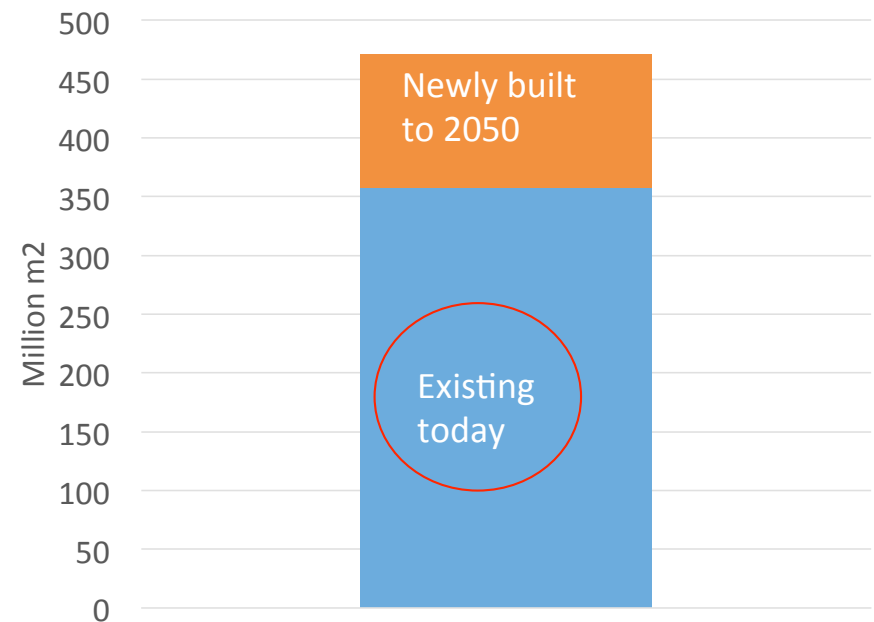

AALBORG UNIVERSITY
DENMARK

1) Projected changes in the **building stock** from today to 2050

Primary energy demand today (2015)

Projected future building stock in 2050

Danish new building requirements

Projected future building stock in 2050

	New residential buildings (kWh/m ² y)	New non-residential buildings (kWh/m ² y)
2015	30 + 1000 / (heated gross floor area)	41+1000 / (heated gross floor area)
2020	20	25
2025	0	0

AALBORG UNIVERSITY
DENMARK

2) Projected changes in the potential future highly-renewable energy system of Denmark

- Today (2015)
 - 70% fossil fuels
 - Over 50% heat supplied by district heating
- Future (2050)
 - 0% fossil fuels
 - Large amount of offshore wind
 - Sector-sector integration to reduce biomass demand & cost
 - End-use demand has a lower primary energy demand

3) Analysis of different heat demand levels in the new buildings

nZEB

Net primary energy demand = Primary energy in – Primary energy out

AALBORG UNIVERSITY
DENMARK

3) Analysis of different heat demand levels in the new buildings

- New buildings
 - 56 kWh/m²
 - 44 kWh/m²
 - 36 kWh/m²
- Existing buildings
 - 132 kWh/m² (same as today)
 - 80 kWh/m² (retrofitting)
- Six scenarios
- E.g. 132 & 56 kWh/m²
- E.g. 44 & 80 kWh/m²

Results - Total heat demand in a 2050 system

Results – Biomass is the limiting factor in a 2050 system

Main points

- Existing building stock in Denmark is large and will remain large in the future
- Energy demand of new buildings will not be too problematic in the future energy system
- The district heating system provides an opportunity to decarbonise the energy system
- Energy can be reduced significantly with system level solutions, i.e. district heating
- European countries should understand their balance between individual and system level solutions, e.g. district heating

AALBORG UNIVERSITY
DENMARK

Further research

- Include all the energy production units of nZEBs
- Investigate the benefits of low-energy nZEBs in the short term to e.g. 2030
- Investigate the total private costs of nZEBs versus cost of energy supply, e.g. district heat supply
- Investigate the change and influence of primary energy factors on the nZEB calculation

AALBORG UNIVERSITY
DENMARK

A photograph of a modern architectural complex featuring a large building with a glass facade and a curved glass bridge over a body of water. The building and bridge are reflected in the calm water. The sky is clear and blue.

Thank you
